(57) Abstract: The invention disclosed herein is directed to methods of identifying a polypeptide suitable for epitope liberation including, for example, the steps of identifying an epitope of interest; providing a substrate polypeptide sequence including the epitope, wherein the substrate polypeptide permits processing by a proteasome; contacting the substrate polypeptide with a composition including the proteasome, under conditions that support processing of the substrate polypeptide by the proteasome; and assaying for liberation of the epitope. The invention further relates to vectors including a housekeeping epitope expression cassette. The housekeeping epitope(s) can be derived from a target-associated antigen, and the housekeeping epitope can be liberatable, that is capable of liberation, from a translation product of the cassette by immunoproteasome processing. The invention also relates to a method of activating a T cell comprising contacting a substrate polypeptide with an APC and contacting the APC with a T cell.

EXPRESSION VECTORS ENCODING EPITOPES OF TARGET-ASSOCIATED ANTIGENS AND METHODS FOR THEIR DESIGN

Background of the Invention

Field of the Invention

[0001] The invention disclosed herein is directed to methods for the design of epitope-encoding vectors for use in compositions, including for example, pharmaceutical compositions capable of inducing an immune response in a subject to whom the compositions are administered. The invention is further directed to the vectors themselves. The epitope(s) expressed using such vectors can stimulate a cellular immune response against a target cell displaying the epitope(s).

Description of the Related Art

[0002] The immune system can be categorized into two discrete effector arms. The first is innate immunity, which involves numerous cellular components and soluble factors that respond to all infectious challenges. The other is the adaptive immune response, which is customized to respond specifically to precise epitopes from infectious agents. The adaptive immune response is further broken down into two effector arms known as the humoral and cellular immune systems. The humoral arm is centered on the production of antibodies by B-lymphocytes while the cellular arm involves the killer cell activity of cytotoxic T Lymphocytes.

[0003] Cytotoxic T Lymphocytes (CTL) do not recognize epitopes on the infectious agents themselves. Rather, CTL detect fragments of antigens derived from infectious agents that are displayed on the surface of infected cells. As a result antigens are visible to CTL only after they have been processed by the infected cell and thus displayed on the surface of the cell.

[0004] The antigen processing and display system on the surface of cells has been well established. CTL recognize short peptide antigens, which are displayed on the surface in non-covalent association with class I major histocompatibility complex molecules (MHC). These class I peptides are in turn derived from the degradation of cytosolic proteins.

Summary of the Invention

[0005] Embodiments of the invention provide expression cassettes, for example, for use in vaccine vectors, which encode one or more embedded housekeeping epitopes, and methods for designing and testing such expression cassettes. Housekeeping epitopes can be liberated from the translation product of such cassettes through proteolytic processing by the immunoproteasome of professional antigen presenting cells (pAPC). In one embodiment of the invention, sequences flanking the housekeeping epitope(s) can be altered to promote cleavage by the immunoproteasome at the desired location(s). Housekeeping epitopes, their uses, and identification are described in U.S. Patent Application Nos. 09/560,465 and 09/561,074 entitled EPITOPE

SYNCHRONIZATION IN ANTIGEN PRESENTING CELLS, and METHOD OF EPITOPE DISCOVERY, respectively; both of which were filed on April 28, 2000.

[0006] Examples of housekeeping epitopes are disclosed in provisional U.S. Patent Applications entitled EPITOPE SEQUENCES, Nos. 60/282,211, filed on April 6, 2001; 60/337,017, filed on November 7, 2001; 60/363210 filed 3/7/02; and 60/409,123, filed on September 5, 2002; and U.S. Application No. 10/117,937, filed on April 4, 2002, which is also entitled EPITOPE SEQUENCES.

[0007] In other embodiments of the invention, the housekeeping epitope(s) can be flanked by arbitrary sequences or by sequences incorporating residues known to be favored in immunoproteasome cleavage sites. As used herein the term "arbitrary sequences" refers to sequences chosen without reference to the native sequence context of the epitope, their ability to promote processing, or immunological function. In further embodiments of the invention multiple epitopes can be arrayed head-to-tail. These arrays can be made up entirely of housekeeping epitopes. Likewise, the arrays can include alternating housekeeping and immune epitopes. Alternatively, the arrays can include housekeeping epitopes flanked by immune epitopes, whether complete or distally truncated. Further, the arrays can be of any other similar arrangement. There is no restriction on placing a housekeeping epitope at the terminal positions of the array. The vectors can additionally contain authentic protein coding sequences or segments thereof containing epitope clusters as a source of immune epitopes. The term "authentic" refers to natural protein sequences.

[0008] Epitope clusters and their uses are described in U.S. Patent application Nos. 09/561,571 entitled EPITOPE CLUSTERS, filed on April 28, 2000; 10/005,905, entitled EPITOPE SYNCHRONIZATION IN ANTIGEN PRESENTING CELLS, filed on November 7, 2001; and 10/026,066, filed on December 7, 2001, also entitled EPITOPE SYNCHRONIZATION IN ANTIGEN PRESENTING CELLS.

[0009] Embodiments of the invention can encompass screening the constructs to determine whether the housekeeping epitope is liberated. In constructs containing multiple housekeeping epitopes, embodiments can include screening to determine which epitopes are liberated. In a preferred embodiment, a vector containing an embedded epitope can be used to immunize HLA transgenic mice and the resultant CTL can be tested for their ability to recognize target cells presenting the mature epitope. In another embodiment, target cells expressing immunoproteasome can be transformed with the vector. The target cell may express immunoproteasome either constitutively, because of treatment with interferon (IFN), or through genetic manipulation, for example. CTL that recognize the mature epitope can be tested for their ability to recognize these target cells. In yet another embodiment, the embedded epitope can be prepared as a synthetic peptide. The synthetic peptide then can be subjected to digestion by an

immunoproteasome preparation *in vitro* and the resultant fragments can be analyzed to determine the sites of cleavage. Such polypeptides, recombinant or synthetic, from which embedded epitopes can be successfully liberated, can also be incorporated into immunogenic compositions.

[0010] The invention disclosed herein relates to the identification of a polypeptide suitable for epitope liberation. One embodiment of the invention, relates to a method of identifying a polypeptide suitable for epitope liberation including, for example, the steps of identifying an epitope of interest; providing a substrate polypeptide sequence including the epitope, wherein the substrate polypeptide permits processing by a proteasome; contacting the substrate polypeptide with a composition including the proteasome, under conditions that support processing of the substrate polypeptide by the proteasome; and assaying for liberation of the epitope.

[0011] The epitope can be embedded in the substrate polypeptide, and in some aspects the substrate polypeptide can include more than one epitope, for example. Also, the epitope can be a housekeeping epitope.

[0012] In one aspect, the substrate polypeptide can be a synthetic peptide. Optionally, the substrate polypeptide can be included in a formulation promoting protein transfer. Alternatively, the substrate polypeptide can be a fusion protein. The fusion protein can further include a protein domain possessing protein transfer activity. Further, the contacting step can include immunization with the substrate polypeptide.

[0013] In another aspect, the substrate polypeptide can be encoded by a polynucleotide. The contacting step can include immunization with a vector including the polynucleotide, for example. The immunization can be carried out in an HLA-transgenic mouse or any other suitable animal, for example. Alternatively, the contacting step can include transforming a cell with a vector including the polynucleotide. In some embodiments the transformed cell can be a target cell that is targeted by CTL for purposes of assaying for proper liberation of epitope.

[0014] The proteasome processing can take place intracellularly, either *in vitro* or *in vivo*. Further, the proteasome processing can take place in a cell-free system.

[0015] The assaying step can include a technique selected from the group including, but not limited to, mass spectrometry, N-terminal pool sequencing, HPLC, and the like. Also, the assaying step can include a T cell target recognition assay. The T cell target recognition assay can be selected from the group including, but not limited to, a cytolytic activity assay, a chromium release assay, a cytokine assay, an ELISPOT assay, tetramer analysis, and the like.

[0016] In still another aspect, the amino acid sequence of the substrate polypeptide including the epitope can be arbitrary. Also, the substrate polypeptide in which the epitope is embedded can be derived from an authentic sequence of a target-associated antigen. Further, the substrate polypeptide in which the epitope is embedded can be conformed to a preferred immune proteasome cleavage site flanking sequence.

[0017] In another aspect, the substrate polypeptide can include an array of additional epitopes. Members of the array can be arranged head-to-tail, for example. The array can include more than one housekeeping epitope. The more than one housekeeping epitope can include copies of the same epitope. The array can include a housekeeping and an immune epitope, or alternating housekeeping and immune epitopes, for example. Also, the array can include a housekeeping epitope positioned between two immune epitopes in an epitope battery. The array can include multiple epitope batteries, so that there are two immune epitopes between each housekeeping epitope in the interior of the array. Optionally, at least one of the epitopes can be truncated distally to its junction with an adjacent epitope. The truncated epitopes can be immune epitopes, for example. The truncated epitopes can have lengths selected from the group including, but not limited to, 9, 8, 7, 6, 5, 4 amino acids, and the like.

[0018] In still another aspect, the substrate polypeptide can include an array of epitopes and epitope clusters. Members of the array can be arranged head-to-tail, for example.

[0019] In yet another aspect, the proteasome can be an immune proteasome.

[0020] Another embodiment of the disclosed invention relates to vectors including a housekeeping epitope expression cassette. The housekeeping epitope(s) can be derived from a target-associated antigen, and the housekeeping epitope can be liberatable, that is capable of liberation, from a translation product of the cassette by immunoproteasome processing.

[0021] In one aspect of the invention the expression cassette can encode an array of two or more epitopes or at least one epitope and at least one epitope cluster. The members of the array can be arranged head-to-tail, for example. Also, the members of the array can be arranged head-to-tail separated by spacing sequences, for example. Further, the array can include a plurality of housekeeping epitopes. The plurality of housekeeping epitopes can include more than one copy of the same epitope or single copies of distinct epitopes, for example. The array can include at least one housekeeping epitope and at least one immune epitope. Also, the array can include alternating housekeeping and immune epitopes. Further, the array includes a housekeeping epitope sandwiched between two immune epitopes so that there are two immune epitopes between each housekeeping epitope in the interior of the array. The immune epitopes can be truncated distally to their junction with the adjacent housekeeping epitope.

[0022] In another aspect, the expression cassette further encodes an authentic protein sequence, or segment thereof, including at least one immune epitope. Optionally, the segment can include at least one epitope cluster. The housekeeping epitope expression cassette and the authentic sequence including at least one immune epitope can be encoded in a single reading frame or transcribed as a single mRNA species, for example. Also, the housekeeping epitope expression cassette and the authentic sequence including at least one immune epitope may not be transcribed as a single mRNA species.

[0023] In yet another aspect, the vector can include a DNA molecule or an RNA molecule. The vector can encode, for example, SEQ ID NO. 4, SEQ ID NO. 17, SEQ ID NO. 20, SEQ ID NO. 26, SEQ ID NO. 27, SEQ ID NO. 29, SEQ ID NO. 33, and the like. Also, the vector can include SEQ ID NO. 9, SEQ ID NO. 19, SEQ ID NO. 21, SEQ ID NO. 30, SEQ ID NO. 34, and the like. Also, the vector can encode SEQ ID NO. 5 or SEQ ID NO. 18, for example.

[0024] In still another aspect, the target-associated antigen can be an antigen derived from or associated with a tumor or an intracellular parasite, and the intracellular parasite can be, for example, a virus, a bacterium, a protozoan, or the like.

[0025] Another embodiment of the invention relates to vectors including a housekeeping epitope identified according to any of the methods disclosed herein, claimed or otherwise. For example, embodiments can relate to vector encoding a substrate polypeptide that includes a housekeeping epitope by any of the methods described herein.

[0026] In one aspect, the housekeeping epitope can be liberated from the cassette translation product by immune proteasome processing

[0027] Another embodiment of the disclosed invention relates to methods of activating a T cell. The methods can include, for example, the steps of contacting a vector including a housekeeping epitope expression cassette with an APC. The housekeeping epitope can be derived from a target-associated antigen, for example, and the housekeeping epitope can be liberatable from a translation product of the cassette by immunoproteasome processing. The methods can further include contacting the APC with a T cell. The contacting of the vector with the APC can occur *in vitro* or *in vivo*.

[0028] Another embodiment of the disclosed invention relates to a substrate polypeptide including a housekeeping epitope wherein the housekeeping epitope can be liberated by immunoproteasome processing in a pAPC.

[0029] Another embodiment of the disclosed invention relates to a method of activating a T cell comprising contacting a substrate polypeptide including a housekeeping epitope with an APC wherein the housekeeping epitope can be liberated by immunoproteasome processing and contacting the APC with a T cell.

Detailed Description of the Preferred Embodiment

Definitions

[0039] Unless otherwise clear from the context of the use of a term herein, the following listed terms shall generally have the indicated meanings for purposes of this description.

[0040] PROFESSIONAL ANTIGEN-PRESENTING CELL (pAPC) – a cell that possesses T cell costimulatory molecules and is able to induce a T cell response. Well characterized pAPCs include dendritic cells, B cells, and macrophages.

[0041] PERIPHERAL CELL – a cell that is not a pAPC.

[0042] HOUSEKEEPING PROTEASOME – a proteasome normally active in peripheral cells, and generally not present or not strongly active in pAPCs.

[0043] IMMUNOPROTEASOME – a proteasome normally active in pAPCs; the immunoproteasome is also active in some peripheral cells in infected tissues or following exposure to interferon.

[0044] EPITOPE – a molecule or substance capable of stimulating an immune response. In preferred embodiments, epitopes according to this definition include but are not necessarily limited to a polypeptide and a nucleic acid encoding a polypeptide, wherein the polypeptide is capable of stimulating an immune response. In other preferred embodiments, epitopes according to this definition include but are not necessarily limited to peptides presented on the surface of cells, the peptides being non-covalently bound to the binding cleft of class I MHC, such that they can interact with T cell receptors (TCR). Epitopes presented by class I MHC may be in immature or mature form. "Mature" refers to an MHC epitope in distinction to any precursor ("immature") that may include or consist essentially of a housekeeping epitope, but also includes other sequences in a primary translation product that are removed by processing, including without

limitation, alone or in any combination, proteasomal digestion, N-terminal trimming, or the action of exogenous enzymatic activities. Thus, a mature epitope may be provided embedded in a somewhat longer polypeptide, the immunological potential of which is due, at least in part, to the embedded epitope; or in its ultimate form that can bind in the MHC binding cleft to be recognized by TCR, respectively.

[0045] MHC EPITOPE – a polypeptide having a known or predicted binding affinity for a mammalian class I or class II major histocompatibility complex (MHC) molecule.

[0046] HOUSEKEEPING EPITOPE – In a preferred embodiment, a housekeeping epitope is defined as a polypeptide fragment that is an MHC epitope, and that is displayed on a cell in which housekeeping proteasomes are predominantly active. In another preferred embodiment, a housekeeping epitope is defined as a polypeptide containing a housekeeping epitope according to the foregoing definition, that is flanked by one to several additional amino acids. In another preferred embodiment, a housekeeping epitope is defined as a nucleic acid that encodes a housekeeping epitope according to the foregoing definitions. Exemplary housekeeping epitopes are provide in U.S. Application No. 10/117,937, filed on April 4, 2002; and U.S. Provisional Application Nos. 60/282,211, filed on April 6, 2001; 60/337,017, filed on November 7, 2001; 60/363210 filed 3/7/02; and 60/409,123, filed on September 5, 2002; all of which are entitled EPITOPE SEQUENCES.

[0047] IMMUNE EPITOPE – In a preferred embodiment, an immune epitope is defined as a polypeptide fragment that is an MHC epitope, and that is displayed on a cell in which immunoproteasomes are predominantly active. In another preferred embodiment, an immune epitope is defined as a polypeptide containing an immune epitope according to the foregoing definition, that is flanked by one to several additional amino acids. In another preferred embodiment, an immune epitope is defined as a polypeptide including an epitope cluster sequence, having at least two polypeptide sequences having a known or predicted affinity for a class I MHC. In yet another preferred embodiment, an immune epitope is defined as a nucleic acid that encodes an immune epitope according to any of the foregoing definitions.

[0048] TARGET CELL – a cell to be targeted by the vaccines and methods of the invention. Examples of target cells according to this definition include but are not necessarily limited to: a neoplastic cell and a cell harboring an intracellular parasite, such as, for example, a virus, a bacterium, or a protozoan. Target cells can also include cells that are targeted by CTL as a part of assays to determine or confirm proper epitope liberation and processing by a cell expressing immunoproteasome, to determine T cell specificity or immunogenicity for a desired epitope.. Such cells may be transfored to express the substrate or liberation sequence, or the cells can simply be pulsed with peptide/epitope.

[0049] TARGET-ASSOCIATED ANTIGEN (TAA) – a protein or polypeptide present in a target cell.

[0050] TUMOR-ASSOCIATED ANTIGENS (TuAA) – a TAA, wherein the target cell is a neoplastic cell.

[0051] HLA EPITOPE – a polypeptide having a known or predicted binding affinity for a human class I or class II HLA complex molecule.

[0052] ANTIBODY – a natural immunoglobulin (Ig), poly- or monoclonal, or any molecule composed in whole or in part of an Ig binding domain, whether derived biochemically or by use of recombinant DNA. Examples include *inter alia,* F(ab), single chain Fv, and Ig variable region-phage coat protein fusions.

[0053] ENCODE – an open-ended term such that a nucleic acid encoding a particular amino acid sequence can consist of codons specifying that (poly)peptide, but can also comprise additional sequences either translatable, or for the control of transcription, translation, or replication, or to facilitate manipulation of some host nucleic acid construct.

[0054] SUBSTANTIAL SIMILARITY – this term is used to refer to sequences that differ from a reference sequence in an inconsequential way as judged by examination of the sequence. Nucleic acid sequences encoding the same amino acid sequence are substantially similar despite differences in degenerate positions or modest differences in length or composition of any non-coding regions. Amino acid sequences differing only by conservative substitution or minor length variations are substantially similar. Additionally, amino acid sequences comprising housekeeping epitopes that differ in the number of N-terminal flanking residues, or immune epitopes and epitope clusters that differ in the number of flanking residues at either terminus, are substantially similar. Nucleic acids that encode substantially similar amino acid sequences are themselves also substantially similar.

[0055] FUNCTIONAL SIMILARITY – this term is used to refer to sequences that differ from a reference sequence in an inconsequential way as judged by examination of a biological or biochemical property, although the sequences may not be substantially similar. For example, two nucleic acids can be useful as hybridization probes for the same sequence but encode differing amino acid sequences. Two peptides that induce cross-reactive CTL responses are functionally similar even if they differ by non-conservative amino acid substitutions (and thus do not meet the substantial similarity definition). Pairs of antibodies, or TCRs, that recognize the same epitope can be functionally similar to each other despite whatever structural differences exist. In testing for functional similarity of immunogenicity one would generally immunize with the "altered" antigen and test the ability of the elicited response (Ab, CTL, cytokine production, etc.) to recognize the target antigen. Accordingly, two sequences may be designed to differ in certain

respects while retaining the same function. Such designed sequence variants are among the embodiments of the present invention.

[0056] EXPRESSION CASSETTE – a polynucleotide sequence encoding a polypeptide, operably linked to a promoter and other transcription and translation control elements, including but not limited to enhancers, termination codons, internal ribosome entry sites, and polyadenylation sites. The cassette can also include sequences that facilitate moving it from one host molecule to another.

[0057] EMBEDDED EPITOPE – an epitope contained within a longer polypeptide, also can include an epitope in which either the N- terminus or the C-terminus is embedded such that the epitope is not in an interior position.

[0058] MATURE EPITOPE – a peptide with no additional sequence beyond that present when the epitope is bound in the MHC peptide-binding cleft.

[0059] EPITOPE CLUSTER – a polypeptide, or a nucleic acid sequence encoding it, that is a segment of a native protein sequence comprising two or more known or predicted epitopes with binding affinity for a shared MHC restriction element, wherein the density of epitopes within the cluster is greater than the density of all known or predicted epitopes with binding affinity for the shared MHC restriction element within the complete protein sequence, and as disclosed in U.S. Patent Application No. 09/561,571 entitled EPITOPE CLUSTERS.

[0060] Substrate or liberation sequence– a designed or engineered sequence comprising or encoding a housekeeping epitope (according to the first of the definitions offered above) embedded in a larger sequence that provides a context allowing the housekeeping epitope to be liberated by immunoproteasomal processing, directly or in combination with N-terminal trimming or other processes.

[0061] Degradation of cytosolic proteins takes place via the ubiquitin-dependent multi-catalytic multi-subunit protease system known as the proteasome. The proteasome degrades cytosolic proteins generating fragments that can then be translocated from the cytosol into the endoplasmic reticulum (ER) for loading onto class I MHC. Such protein fragments shall be referred to as class I peptides. The peptide loaded MHC are subsequently transported to the cell surface where they can be detected by CTL.

[0062] The multi-catalytic activity of the proteasome is the result of its multi-subunit structure. Subunits are expressed from different genes and assembled post-translationally into the proteasome complex. A key feature of the proteasome is its bimodal activity, which enables it to exert its protease, or cleavage function, with two discrete kinds of cleavage patterns. This bimodal action of the proteasome is extremely fundamental to understanding how CTL are targeted to recognize peripheral cells in the body and how this targeting requires synchronization between the immune system and the targeted cells.

[0063] The housekeeping proteasome is constitutively active in all peripheral cells and tissues of the body. The first mode of operation for the housekeeping proteasome is to degrade cellular protein, recycling it into amino acids. Proteasome function is therefore a necessary activity for cell life. As a corollary to its housekeeping protease activity, however, class I peptides generated by the housekeeping proteasome are presented on all of the peripheral cells of the body.

[0064] The proteasome's second mode of function is highly exclusive and occurs specifically in pAPCs or as a consequence of a cellular response to interferons (IFNs). In its second mode of activity the proteasome incorporates unique subunits, which replace the catalytic subunits of the constitutive housekeeping proteasome. This "modified" proteasome has been called the immunoproteasome, owing to its expression in pAPC and as a consequence of induction by IFN in body cells.

[0065] APC define the repertoire of CTL that recirculate through the body and are potentially active as killer cells. CTL are activated by interacting with class I peptide presented on the surface of a pAPC. Activated CTL are induced to proliferate and caused to recirculate through the body in search of diseased cells. This is why the CTL response in the body is defined specifically by the class I peptides produced by the pAPC. It is important to remember that pAPCs express the immunoproteasome, and that as a consequence of the bimodal activity of the proteasome, the cleavage pattern of proteins (and the resultant class I peptides produced) are different from those in peripheral body cells which express housekeeping proteasome. The differential proteasome activity in pAPC and peripheral body cells, therefore, is important to consider during natural infection and with therapeutic CTL vaccination strategies.

[0066] All cells of the body are capable of producing IFN in the event that they are infected by a pathogen such as a virus. IFN production in turn results in the expression of the immunoproteasome in the infected cell. Viral antigens are thereby processed by the immunoproteasome of the infected cell and the consequent peptides are displayed with class I MHC on the cell surface. At the same time, pAPC are sequestering virus antigens and are processing class I peptides with their immunoproteasome activity, which is normal for the pAPC cell type. The CTL response in the body is being stimulated specifically by the class I peptides produced by the pAPC. Fortunately, the infected cell is also producing class I peptides from the immunoproteasome, rather than the normal housekeeping proteasome. Thus, virus-related class I peptides are being produced that enable detection by the ensuing CTL response. The CTL immune response is induced by pAPC, which normally produce different class I peptides compared to peripheral body cells, owing to different proteasome activity. Therefore, during infection there is epitope synchronization between the infected cell and the immune system.

[0067] This is not the case with tumors and chronic viruses, which block the interferon system. For tumors there is no infection in the tumor cell to induce the

immunoproteasome expression, and chronic virus infection either directly or indirectly blocks immunoproteasome expression. In both cases the diseased cell maintains its display of class I peptides derived from housekeeping proteasome activity and avoids effective surveillance by CTL.

[0068] In the case of therapeutic vaccination to eradicate tumors or chronic infections, the bimodal function of the proteasome and its differential activity in APC and peripheral cells of the body is significant. Upon vaccination with protein antigen, and before a CTL response can occur, the antigen must be acquired and processed into peptides that are subsequently presented on class I MHC on the pAPC surface. The activated CTL recirculate in search of cells with similar class I peptide on the surface. Cells with this peptide will be subjected to destruction by the cytolytic activity of the CTL. If the targeted diseased cell does not express the immunoproteasome, which is present in the pAPC, then the epitopes are not synchronized and CTL fail to find the desired peptide target on the surface of the diseased cell.

[0069] Preferably, therapeutic vaccine design takes into account the class I peptide that is actually present on the target tissue. That is, effective antigens used to stimulate CTL to attack diseased tissue are those that are naturally processed and presented on the surface of the diseased tissue. For tumors and chronic infection this generally means that the CTL epitopes are those that have been processed by the housekeeping proteasome. In order to generate an effective therapeutic vaccine, CTL epitopes are identified based on the knowledge that such epitopes are, in fact, produced by the housekeeping proteasome system. Once identified, these epitopes, embodied as peptides, can be used to successfully immunize or induce therapeutic CTL responses against housekeeping proteasome expressing target cells in the host.

[0070] However, in the case of DNA vaccines, there can be an additional consideration. The immunization with DNA requires that APCs take up the DNA and express the encoded proteins or peptides. It is possible to encode a discrete class I peptide on the DNA. By immunizing with this construct, APCs can be caused to express a housekeeping epitope, which is then displayed on class I MHC on the surface of the cell for stimulating an appropriate CTL response. Constructs for generation of proper termini of housekeeping epitopes have been described in U.S. Patent application No. 09/561,572 entitled EXPRESSION VECTORS ENCODING EPITOPES OF TARGET-ASSOCIATED ANTIGENS, filed on April 28, 2000.

[0071] Embodiments of the invention provide expression cassettes that encode one or more embedded housekeeping epitopes, and methods for designing and testing such expression cassettes. The expression cassettes and constructs can encode epitopes, including housekeeping epitopes, derived from antigens that are associated with targets. Housekeeping epitopes can be liberated from the translation product(s) of the cassettes. For example, in some embodiments of the invention, the housekeeping epitope(s) can be flanked by arbitrary sequences or by sequences incorporating residues known to be favored in immunoproteasome cleavage sites. In further

embodiments of the invention multiple epitopes can be arrayed head-to-tail. In some embodiments, these arrays can be made up entirely of housekeeping epitopes. Likewise, the arrays can include alternating housekeeping and immune epitopes. Alternatively, the arrays can include housekeeping epitopes flanked by immune epitopes, whether complete or distally truncated. In some preferred embodiments, each housekeeping epitope can be flanked on either side by an immune epitope, such that an array of such arrangements has two immune epitopes between each housekeeping epitope. Further, the arrays can be of any other similar arrangement. There is no restriction on placing a housekeeping epitope at the terminal positions of the array. The vectors can additionally contain authentic protein coding sequences or segments thereof containing epitope clusters as a source of immune epitopes.

[0072] Several disclosures make reference to polyepitopes or string-of-bead arrays. *See*, for example, WO0119408A1, March 22, 2001; WO9955730A2, November 4, 1999; WO0040261A2, July 13, 2000; WO9603144A1, February 8, 1996; EP1181314A1, February 27, 2002; WO0123577A3, April 5; US6074817, June 13, 2000; US5965381, October 12, 1999; WO9741440A1, November 6, 1997; US6130066, October 10, 2000; US6004777, December 21, 1999; US5990091, November 23, 1999; WO9840501A1, September 17, 1998; WO9840500A1, September 17, 1998; WO0118035A2, March 15, 2001; WO02068654A2, September 6, 2002; WO0189281A2, November 29, 2001; WO0158478A, August 16, 2001; EP1118860A1, July 25, 2001; WO0111040A1, February 15, 2001; WO0073438A1, December 7, 2000; WO0071158A1, November 30, 2000; WO0066727A1, November 9, 2000; WO0052451A1, September 8, 2000; WO0052157A1, September 8, 2000; WO0029008A2, May 25, 2000; WO0006723A1, February 10, 2000. [0073] One important feature that the disclosures in the preceding paragraph all share is their lack of appreciation for the desirability of regenerating housekeeping epitopes when the construct is expressed in a pAPC. This understanding was not apparent until the present invention. Embodiments of the invention include sequences, that when processed by an immune proteasome, liberate or generate a housekeeping epitope. Embodiments of the invention also can liberate or generate such epitopes in immunogenically effective amounts. Accordingly, while the preceding references contain disclosures relating to polyepitope arrays, none is enabling of the technology necessary to provide or select a polyepitope capable of liberating a housekeeping epitope by action of an immunoproteasome in a pAPC. In contrast, embodiments of the instant invention are based upon a recognition of the desirability of achieving this result. Accordingly, embodiments of the instant invention include any nucleic acid construct that encodes a polypeptide containing at least one housekeeping epitope provided in a context that promotes its generation via immunoproteasomal activity, whether the housekeeping epitope is embedded in a string-of-beads array or some other arrangement. Some embodiments of the invention include uses of one or more of the nucleic acid constructs or their products that are specifically disclosed in any one or more of the above-listed references. Such uses include, for example, screening a polyepitope for proper liberation context of a housekeeping epitope and/or an immune epitope, designing an effective immunogen capable of causing presentation of a housekeeping epitope and/or an immune epitope on a pAPC, immunizing a patient, and the like. Alternative embodiments include use of only a subset of such nucleic acid constructs or a single such construct, while specifically excluding one or more other such constructs, for any of the purposes disclosed herein. Some preferred embodiments employ these and/or other nucleic acid sequences encoding polyepitope arrays alone or in combination. For example, some embodiments exclude use of polyepitope arrays from one or more of the above-mentioned references. Other embodiments may exclude any combination or all of the polyepitope arrays from the above-mentioned references collectively. Some embodiments include viral and/or bacterial vectors encoding polyepitope arrays, while other embodiments specifically exclude such vectors. Such vectors can encode carrier proteins that may have some immunostimulatory effect. Some embodiments include such vectors with such immunostimulatory/immunopotentiating effects, as opposed to immunogenic effects, while in other embodiments such vectors may be included. Further, in some instances viral and bacterial vectors encode the desired epitope as a part of substantially complete proteins which are not associated with the target cell. Such vectors and products are included in some embodiments, while excluded from others. Some embodiments relate to repeated administration of vectors. In some of those embodiments, nonviral and nonbacterial vectors are included. Likewise, some embodiments

include arrays that contain extra amino acids between epitopes, for example anywhere from 1-6 amino acids, or more, in some embodiments, while other embodiments specifically exclude such arrays.

[0074] Embodiments of the present invention also include methods, uses, therapies, and compositions directed to various types of targets. Such targets can include, for example, neoplastic cells such as those listed below, for example; and cells infected with any virus, bacterium, protozoan, fungus, or other agents, examples of which are listed below, in Tables 1-5, or which are disclosed in any of the references listed above. Alternative embodiments include the use of only a subset of such neoplastic cells and infected cells listed below, in Tables 1-5, or in any of the references disclosed herein, or a single one of the neoplastic cells or infected cells, while specifically excluding one or more other such neoplastic cells or infected cells, for any of the purposes disclosed herein. The following are examples of neoplastic cells that can be targeted: human sarcomas and carcinomas, e.g., fibrosarcoma, myxosarcoma, liposarcoma, chondrosarcoma, osteogenic sarcoma, chordoma, angiosarcoma, endotheliosarcoma, lymphangiosarcoma, lymphangioendotheliosarcoma, synovioma, mesothelioma, Ewing's tumor, leiomyosarcoma, rhabdomyosarcoma, colon carcinoma, pancreatic cancer, breast cancer, ovarian cancer, prostate cancer, squamous cell carcinoma, basal cell carcinoma, adenocarcinoma, sweat gland carcinoma, sebaceous gland carcinoma, papillary carcinoma, papillary adenocarcinomas, cystadenocarcinoma, medullary carcinoma, bronchogenic carcinoma, renal cell carcinoma, hepatoma, bile duct carcinoma, choriocarcinoma, seminoma, embryonal carcinoma, Wilms' tumor, cervical cancer, testicular tumor, lung carcinoma, small cell lung carcinoma, bladder carcinoma, epithelial carcinoma, glioma, astrocytoma, medulloblastoma, craniopharyngioma, ependymoma, pinealoma, hemangioblastoma, acoustic neuroma, oligodendroglioma, meningioma, melanoma, neuroblastoma, retinoblastoma; leukemias, e.g., acute lymphocytic leukemia and acute myelocytic leukemia (myeloblastic, promyelocytic, myelomonocytic, monocytic and erythroleukemia); chronic leukemia (chronic myelocytic (granulocytic) leukemia and chronic lymphocytic leukemia); and polycythemia vera, lymphoma (Hodgkin's disease and non Hodgkin's disease), multiple myeloma, Waldenstrom's macroglobulinemia, heavy chain disease, hepatocellular cancer, brain cancer, stomach cancer, liver cancer, and the like. Examples of infectious agents that infect the target cells can include the following: adenovirus, cytomegalovirus, Epstein-Barr virus, herpes simplex virus 1, herpes simplex virus 2, human herpesvirus 6, varicella-zoster virus, hepatitis B virus, hepatitis D virus, papilloma virus, parvovirus B19, polyomavirus BK, polyomavirus JC, hepatitis C virus, measles virus, rubella virus, human immunodeficiency virus (HIV), human T cell leukemia virus I, human T cell leukemia virus II, *Chlamydia*, *Listeria*, *Salmonella*, *Legionella*, *Brucella*, *Coxiella*, *Rickettsia*, *Mycobacterium*, *Leishmania*, *Trypanasoma*, *Toxoplasma*, *Plasmodium*, and the like. Exemplary infectious agents and neoplastic cells are also included in Tables 1-5 below.

[0075] Furthermore the targets can include neoplastic cells described in or cells infected by agents that are described in any of the following references: Jäger, E. et al., "Granulocyte-macrophage-colony-stimulating factor enhances immune responses to melanoma-associated peptides *in vivo*," *Int. [0076] Additional embodiments of the invention include methods, uses, therapies, and compositions relating to a particular antigen, whether the antigen is derived from, for example, a target cell or an infective agent, such as those mentioned above. Some preferred embodiments employ the antigens listed herein, in Tables 1-5, or in the list below, alone, as subsets, or in any combination. For example, some embodiments exclude use of one or more of those antigens. Other embodiments may exclude any combination or all of those antigens. Several examples of such antigens include MelanA (MART-I), gp100 (Pmel 17), tyrosinase, TRP-1, TRP-2, MAGE-1, MAGE-3, BAGE, GAGE-1, GAGE-2, CEA, RAGE, NY-ESO, SCP-1, Hom/Mel-40, PRAME, p53, H-Ras, HER-2/neu, BCR-ABL, E2A-PRL, H4-RET, IGH-IGK, MYL-RAR, Epstein Barr virus antigens, EBNA, human papillomavirus (HPV) antigens E6 and E7, TSP-180, MAGE-4, MAGE-5, MAGE-6, p185erbB2, p180erbB-3, c-met, nm-23H1, PSA, TAG-72-4, CAM 17.1, NuMa, K-ras, β-Catenin, CDK4, Mum-1, p16, as well as any of those set forth in the above mentioned references. Other antigens are included in Tables 1-4 below.

[0077] Further embodiments include methods, uses, compositions, and therapies relating to epitopes, including, for example those epitopes listed in Tables 1-5. These epitopes can be useful to flank housekeeping epitopes in screening vectors, for example. Some embodiments

include one or more epitopes from Tables 1-5, while other embodiments specifically exclude one or more of such epitopes or combinations thereof.

Table 1

Table 3 sets forth additional antigens useful in the invention that are available from the Ludwig Cancer Institute. The Table refers to patents in which the identified antigens can be found. TRA refers to the tumor-related antigen and the LUD No. refers to the Ludwig Institute number.

[0078] Still further embodiments are directed to methods, uses, therapies and compositions related to epitopes with specificity for MHC, including, for example, those listed in Tables 6-10. Other embodiments include one or more of the MHCs listed in Tables 6-10, including combinations of the same, while other embodiments specifically exclude any one or more of the MHCs or combinations thereof. Tables 8-10 include frequencies for the listed HLA antigens.

[a]Gene frequency.
[b]Standard error.

[0080] It can be desirable to express housekeeping peptides in the context of a larger protein. Processing can be detected even when a small number of amino acids are present beyond the terminus of an epitope. Small peptide hormones are usually proteolytically processed from longer translation products, often in the size range of approximately 60-120 amino acids. This fact has led some to assume that this is the minimum size that can be efficiently translated. In some embodiments, the housekeeping peptide can be embedded in a translation product of at least about 60 amino acids, in others 70, 80, 90 amino acids, and in still others 100, 110 or 120 amino acids, for example. In other embodiments the housekeeping peptide can be embedded in a translation product of at least about 50, 30, or 15 amino acids.

[0081] Due to differential proteasomal processing, the immunoproteasome of the pAPC produces peptides that are different from those produced by the housekeeping proteasome in peripheral body cells. Thus, in expressing a housekeeping peptide in the context of a larger protein, it is preferably expressed in the pAPC in a context other than its full-length native sequence, because, as a housekeeping epitope, it is generally only efficiently processed from the native protein by the housekeeping proteasome, which is not active in the pAPC. In order to encode the housekeeping epitope in a DNA sequence encoding a larger polypeptide, it is useful to find flanking areas on either side of the sequence encoding the epitope that permit appropriate cleavage by the immunoproteasome in order to liberate that housekeeping epitope. Such a sequence promoting

appropriate processing is referred to hereinafter as having substrate or liberation sequence function. Altering flanking amino acid residues at the N-terminus and C-terminus of the desired housekeeping epitope can facilitate appropriate cleavage and generation of the housekeeping epitope in the pAPC. Sequences embedding housekeeping epitopes can be designed *de novo* and screened to determine which can be successfully processed by immunoproteasomes to liberate housekeeping epitopes.

[0082] Alternatively, another strategy is very effective for identifying sequences allowing production of housekeeping epitopes in APC. A contiguous sequence of amino acids can be generated from head to tail arrangement of one or more housekeeping epitopes. A construct expressing this sequence is used to immunize an animal, and the resulting T cell response is evaluated to determine its specificity to one or more of the epitopes in the array. These immune responses indicate housekeeping epitopes that are processed in the pAPC effectively. The necessary flanking areas around this epitope are thereby defined. The use of flanking regions of about 4-6 amino acids on either side of the desired peptide can provide the necessary information to facilitate proteasome processing of the housekeeping epitope by the immunoproteasome. Therefore, a substrate or liberation sequence of approximately 16-22 amino acids can be inserted into, or fused to, any protein sequence effectively to result in that housekeeping epitope being produced in an APC. In some embodiments, a broader context of a substrate sequence can also influence processing. In such embodiments, comparisons of a liberaton sequence in a variety of contexts can be useful in further optimizing a particular substrate sequence. In alternate embodiments the whole head-to-tail array of epitopes, or just the epitopes immediately adjacent to the correctly processed housekeeping epitope can be similarly transferred from a test construct to a vaccine vector.

[0083] In a preferred embodiment, the housekeeping epitopes can be embedded between known immune epitopes, or segments of such, thereby providing an appropriate context for processing. The abutment of housekeeping and immune epitopes can generate the necessary context to enable the immunoproteasome to liberate the housekeeping epitope, or a larger fragment, preferably including a correct C-terminus. It can be useful to screen constructs to verify that the desired epitope is produced. The abutment of housekeeping epitopes can generate a site cleavable by the immunoproteasome. Some embodiments of the invention employ known epitopes to flank housekeeping epitopes in test substrates; in others, screening as described below is used, whether the flanking regions are arbitrary sequences or mutants of the natural flanking sequence, and whether or not knowledge of proteasomal cleavage preferences are used in designing the substrates.

[0084] Cleavage at the mature N-terminus of the epitope, while advantageous, is not required, since a variety of N-terminal trimming activities exist in the cell that can generate the

mature N-terminus of the epitope subsequent to proteasomal processing. It is preferred that such N-terminal extension be less than about 25 amino acids in length and it is further preferred that the extension have few or no proline residues. Preferably, in screening, consideration is given not only to cleavage at the ends of the epitope (or at least at its C-terminus), but consideration also can be given to ensure limited cleavage within the epitope.

[0085] Shotgun approaches can be used in designing test substrates and can increase the efficiency of screening. In one embodiment multiple epitopes can be assembled one after the other, with individual epitopes possibly appearing more than once. The substrate can be screened to determine which epitopes can be produced. In the case where a particular epitope is of concern, a substrate can be designed in which it appears in multiple different contexts. When a single epitope appearing in more than one context is liberated from the substrate additional secondary test substrates, in which individual instances of the epitope are removed, disabled, or are unique, can be used to determine which are being liberated and truly confer substrate or liberation sequence function.

[0086] Several readily practicable screens exist. A preferred *in vitro* screen utilizes proteasomal digestion analysis, using purified immunoproteasomes, to determine if the desired housekeeping epitope can be liberated from a synthetic peptide embodying the sequence in question. The position of the cleavages obtained can be determined by techniques such as mass spectrometry, HPLC, and N-terminal pool sequencing; as described in greater detail in U.S. Patent Application Nos. 09/561,074, 09/560,465 and 10/117,937, and Provisional U.S. Patent Application Nos. 60/282,211, 60/337,017, and 60/363, 210.

[0087] Alternatively, *in vivo* and cell-based screens such as immunization or target sensitization can be employed. For immunization a nucleic acid construct capable of expressing the sequence in question is used. Harvested CTL can be tested for their ability to recognize target cells presenting the housekeeping epitope in question. Such targets cells are most readily obtained by pulsing cells expressing the appropriate MHC molecule with synthetic peptide embodying the mature housekeeping epitope. Alternatively, immunization can be carried out using cells known to express housekeeping proteasome and the antigen from which the housekeeping epitope is derived, either endogenously or through genetic engineering. To use target sensitization as a screen, CTL, or preferably a CTL clone, that recognizes the housekeeping epitope can be used. In this case it is the target cell that expresses the embedded housekeeping epitope (instead of the pAPC during immunization) and it must express immunoproteasome. Generally, the cell or target cell can be transformed with an appropriate nucleic acid construct to confer expression of the embedded

housekeeping epitope. Loading with a synthetic peptide embodying the embedded epitope using peptide loaded liposomes, or complexed with cationic lipid protein transfer reagents such as BIOPORTER™ (Gene Therapy Systems, San Diego, CA), represents an alternative.

[0088] Once sequences with substrate or liberation sequence function are identified they can be encoded in nucleic acid vectors, chemically synthesized, or produced recombinantly. In any of these forms they can be incorporated into immunogenic compositions. Such compositions can be used *in vitro* in vaccine development or in the generation or expansion of CTL to be used in adoptive immunotherapy. *In vivo* they can be used to induce, amplify or sustain and active immune response. The uptake of polypeptides for processing and presentation can be greatly enhanced by packaging with cationic lipid, the addition of a tract of cationic amino acids such as poly-L-lysine (Ryser, H.J. et al., *J. Cell Physiol.* 113:167-178, 1982; Shen, W.C. & Ryser, H.J., *Proc. Natl. Aced. Sci. USA* 75:1872-1876, 1978), the incorporation into branched structures with importation signals (Sheldon, K. et al., *Proc. Natl. Aced. Sci. USA* 92:2056-2060, 1995), or mixture with or fusion to polypeptides with protein transfer function including peptide carriers such as pep-1 (Morris, M.C., et al., *Nat. Biotech.* 19:1173-1176, 2001), the PreS2 translocation motif of hepatitis B virus surface antigen, VP22 of herpes viruses, and HIV-TAT protein (Oess, S. & Hildt, E., *Gene Ther.* 7:750-758, 2000; Ford, K.G., et al., *Gene Ther.* 8:1-4, 2001; Hung, C.F. et al., *J. Virol.* 76:2676-2682, 2002; Oliveira, S.C., et a;. *Hum. Gene Ther.* 12:1353-1359, 2001; Normand, N. et al., *J. Biol. Chem.* 276:15042-15050, 2001; Schwartz, J.J. & Zhang, S., *Curr. Opin. Mol. Ther.* 2:162-167, 2000; Elliot G., 7 Hare, P. Cell 88:223-233, 1997), among other methodologies. Particularly for fusion proteins the immunogen can be produced in culture and the purified protein administered or, in the alternative, the nucleic acid vector can be administered so that the immunogen is produced and secreted by cells transformed *in vivo*. In either scenario the transport function of the fusion protein facilitates uptake by pAPC.

EXAMPLES

Example 1

[0089] A recombinant DNA plasmid vaccine, pMA2M, which encodes one polypeptide with an HLA A2-specific CTL epitope ELAGIGILTV (SEQ ID NO. 1) from melan-A (26-35A27L), and a portion (amino acids 31-96) of melan-A (SEQ ID NO. 2) including the epitope clusters at amino acids 31-48 and 56-69, was constructed. These clusters were previously disclosed in U.S. Patent Application No. 09/561,571 entitled EPITOPE CLUSTERS. Flanking the defined melan-A CTL epitope are short amino acid sequences derived from human tyrosinase (SEQ ID NO. 3) to facilitate liberation of the melan-A housekeeping epitope by processing by the immunoproteasome.

In addition, these amino acid sequences represent potential CTL epitopes themselves. The cDNA sequence for the polypeptide in the plasmid is under the control of promoter/enhancer sequence from cytomegalovirus (CMVp) (see Figure 1), which allows efficient transcription of messenger for the polypeptide upon uptake by APCs. The bovine growth hormone polyadenylation signal (BGH polyA) at the 3' end of the encoding sequence provides a signal for polyadenylation of the messenger to increase its stability as well as for translocation out of nucleus into the cytoplasm for translation. To facilitate plasmid transport into the nucleus after uptake, a nuclear import sequence (NIS) from simian virus 40 (SV40) has been inserted in the plasmid backbone. The plasmid carries two copies of a CpG immunostimulatory motif, one in the NIS sequence and one in the plasmid backbone. Lastly, two prokaryotic genetic elements in the plasmid are responsible for amplification in *E.coli*, the kanamycin resistance gene (Kan R) and the pMB1 bacterial origin of replication.

SUBSTRATE or LIBERATION sequence

[0090] The amino acid sequence of the encoded polypeptide (94 amino acid residues in length) (SEQ ID NO. 4) containing a 28 amino acid substrate or liberation sequence at its N-terminus (SEQ ID NO. 5) is given below:

[0091] MLLAVLYCL-ELAGIGILTV-YMDGTMSQV-GILTVILGVLLLIGCWYCRRRNGYRALMDKSLHVGTQCALTRRCPQEGFDHRDSKVSLQEK NCEPV

[0092] The first 9 amino acid residues are derived from tyrosinase$_{1-9}$ (SEQ ID NO. 6), the next ten constitute melan-A (26-35A27L) (SEQ ID NO. 1), and amino acid residues 20 to 29 are derived from tyrosinase$_{369-377}$ (SEQ ID NO. 7). These two tyrosinase nonamer sequences both represent potential HLA A2-specific CTL epitopes. Amino acid residues 10-19 constitute melan-A (26-35A27L) an analog of an HLA A2-specific CTL epitope from melan-A, EAAGIGILTV (SEQ ID NO. 8), with an elevated potency in inducing CTL responses during *in vitro* immunization of human PBMC and *in vivo* immunization in mice. The segment of melan-A constituting the rest of the polypeptide (amino acid residues 30 to 94) contain a number of predicted HLA A2-specific epitopes, including the epitope clusters cited above, and thus can be useful in generating a response to immune epitopes as described at length in the patent applications 'Epitope Synchronization in Antigen Presenting Cells' and 'Epitope Clusters'. This region was also included to overcome any difficulties

that can be associated with the expression of shorter sequences. A drawing of pMA2M is shown in Figure 1.

Plasmid construction

[0093] A pair of long complementary oligonucleotides was synthesized which encoded the first 30 amino acid residues. In addition, upon annealing, these oligonucleotides generated the cohensive ends of *Afl* II at the 5' end and that of *EcoR* I at the 3' end. The melan A_{31-96} region was amplified with PCR using oligonucleotides carrying restriction sites for *EcoR* I at the 5' end and *Not* I at the 3' end. The PCR product was digested with *EcoR* I and *Not* I and ligated into the vector backbone, described in Example 1, that had been digested with *Afl* II and *Not* I, along with the annealed oligonucleotides encoding the amino terminal region in a three-fragment ligation. The entire coding sequence was verified by DNA sequencing. The sequence of the entire insert, from the *Afl* II site at the 5' end to the *Not* I site at the 3' end is disclosed as SEQ ID NO. 9. Nucleotides 12-293 encode the polypeptide.

Example 2

[0094] Three vectors containing melan-A (26-35A27L) (SEQ ID NO. 1) as an embedded housekeeping epitope were tested for their ability to induce a CTL response to this epitope in HLA-A2 transgenic HHD mice (Pascolo et al. *J. Exp. Med.* 185:2043-2051, 1997). One of the vectors was pMA2M described above (called pVAXM3 in Figure 3). In pVAXM2 the same basic group of 3 epitopes was repeated several times with the flanking epitopes truncated by differing degrees in the various repeats of the array. Specifically the cassette consisted of:

[0095] M-Tyr(5-9)-ELA-Tyr(369-373)-Tyr(4-9)-ELA-Tyr(369-374)-Tyr(3-9)-ELA-Tyr(369-375)-Tyr(2-9)-ELA

(SEQ ID NO. 10)

[0096] where ELA represents melan-A (26-35A27L) (SEQ ID NO. 1). This cassette was inserted in the same plasmid backbone as used for pVAXM3. The third, pVAXM1 is identical to pVAXM2 except that the epitope array is followed by an IRES (internal ribosome entry site for encephalomyocarditis virus) linked to a reading frame encoding melan-A 31-70.

[0097] Four groups of three HHD A2.1 mice were injected intranodally in surgically exposed inguinal lymph nodes with 25 µl of 1 mg/ml plasmid DNA in PBS on days 0, 3, and 6, each group receiving one of the three vectors or PBS alone. On day 14 the spleens were harvested and restimulated *in vitro* one time with 3-day LPS blasts pulsed with peptide (melan-A (26-

35A27L)(SEQ ID NO. 1)). The *in vitro* cultures were supplemented with Rat T-Stim (Collaborative Biomedical Products) on the 3rd day and assayed for cytolytic activity on the 7th day using a standard ^{51}Cr-release assay. Figures 2 to 5 show % specific lysis obtained using the cells immunized with PBS, pVAXM1, pVAXM2, and pVAXM3, respectively on T2 target cells and T2 target cells pulsed with melan-A (26-35A27L) (ELA) (SEQ ID NO. 1). All three vectors generated strong CTL responses. These data indicated that the plasmids have been taken up by APCs, the encoded polypeptide has been synthesized and proteolytically processed to produce the decamer epitope in question (that is, it had substrate or liberation sequence function), and that the epitope became HLA-A2 bound for presentation. Also, an isolated variant of pVAXM2, that terminates after the 55th amino acid, worked similarly well as the full length version (data not shown). Whether other potential epitopes within the expression cassette can also be produced and be active in inducing CTL responses can be determined by testing for CTL activity against target cells pulsed with corresponding synthetic peptides.

Example 3

An NY-ESO-1 (SEQ ID NO. 11) SUBSTRATE/LIBERATION Sequence

[0098] Six other epitope arrays were tested leading to the identification of a substrate/liberation sequence for the housekeeping epitope NY-ESO-$1_{157-165}$ (SEQ ID NO. 12). The component epitopes of the arrays were:

[0099]	SSX-2_{41-49}:	KASEKIFYV	(SEQ ID NO. 13)	Array element A
[0100]	NY-ESO-$1_{157-165}$:	SLLMWITQC	(SEQ ID NO. 12)	Array element B
[0101]	NY-ESO-$1_{163-171}$:	TQCFLPVFL	(SEQ ID NO. 14)	Array element C
[0102]	$PSMA_{288-297}$:	GLPSIPVHPI	(SEQ ID NO. 15)	Array element D
[0103]	TYR_{4-9}:	AVLYCL	(SEQ ID NO. 16)	Array element E

[0104] The six arrays had the following arrangements of elements after starting with an initiator methionine:

[0105]	pVAX-PC-A:	B-A-D-D-A-B-A-A
[0106]	pVAX-PC-B:	D-A-B-A-A-D-B-A
[0107]	pVAX-PC-C:	E-A-D-B-A-B-E-A-A
[0108]	pVAX-BC-A:	B-A-C-B-A-A-C-A
[0109]	pVAX-BC-B:	C-A-B-C-A-A-B-A

[0110] pVAX-BC-C: E-A-A-B-C-B-A-A

[0111] These arrays were inserted into the same vector backbone described in the examples above. The plasmid vectors were used to immunize mice essentially as described in Example 2 and the resulting CTL were tested for their ability to specifically lyse target cells pulsed with the peptide NY-ESO-1 157-165, corresponding to element B above. Both pVAX-PC-A and pVAX-BC-A were found to induce specific lytic activity. Comparing the contexts of the epitope (element B) in the various arrays, and particularly between pVAX-PC-A and pVAX-BC-A, between pVAX-PC-A and pVAX-PC-B, and between pVAX-BC-A and pVAX-BC-C, it was concluded that it was the first occurrence of the epitope in pVAX-PC-A and pVAX-BC-A that was being correctly processed and presented. In other words an initiator methionine followed by elements B-A constitute a substrate/liberation sequence for the presentation of element B. On this basis a new expression cassette for use as a vaccine was constructed encoding the following elements:

[0112] An initiator methionine,

[0113] NY-ESO-$1_{157\text{-}165}$ (**bold**) – a housekeeping epitope,

[0114] $SSX2_{41\text{-}49}$ (*italic*) – providing appropriate context for processing, and

[0115] NY-ESO-$1_{77\text{-}180}$ – to avoid "short sequence" problems and provide immune epitopes.

[0116] Thus the construct encodes the amino acid sequence:

[0117] M-**SLLMWITQC**-*KASEKIFYV*-
RCGARGPESRLLEFYLAMPFATPMEAELARRSLAQDAPPLPVPGVLLKEFTVSGNILTIRLTA
ADHRQLQLSISSCLQQLSLLMWITQCFLPVFLAQPPSGQRR (SEQ ID NO. 17) and MSLLMWITQCKASEKIFYV (SEQ ID NO. 18) constitutes the liberation or substrate sequence. A polynucleotide encoding SEQ ID NO. 17 (SEQ ID NO. 19: nucleotides 12-380) was inserted into the same plasmid backbone as used for pMA2M generating the plasmid pN157.

Example 4

[0118] A construct similar to pN157 containing the whole epitope array from pVAX-PC-A was also made and designated pBPL. Thus the encoded amino acid sequence in pBPL is:

[0119] M-**SLLMWITQC**-*KASEKIFYV*-GLPSIPVHPI-GLPSIPVHPI-*KASEKIFYV*-
SLLMWITQC-*KASEKIFYV-KASEKIFYV*-
RCGARGPESRLLEFYLAMPFATPMEAELARRSLAQDAPPLPVPGVLLKEFTVSGNILTIRLTA
ADHRQLQLSISSCLQQLSLLMWITQCFLPVFLAQPPSGQRR (SEQ ID NO. 20).

[0120] SEQ ID NO. 21 is the polynucleotide encoding SEQ ID NO. 20 used in pBPL.

[0121] A portion of SEQ ID NO. 20, *IKASEKIFYV*SLLMWITQC*KASEKIFYV*K (SEQ ID NO. 22) was made as a synthetic peptide and subjected to *in vitro* proteasomal digestion analysis with human immunoproteasome, utilizing both mass spectrometry and N-terminal pool sequencing. The identification of a cleavage after the C residue indicates that this segment of the construct can function as a substrate or liberation sequence for NY-ESO-$1_{157-165}$ (SEQ ID NO. 12) epitope (see Figure 6). Figure 7 shows the differential processing of the SLLMWITQC epitope (SEQ ID NO. 12) in its native context where the cleavage following the C is more efficiently produced by housekeeping than immunoproteasome. The immunoproteasome also produces a major cleavage internal to the epitope, between the T and the Q when the epitope is in its native context, but not in the context of SEQ ID NO. 22 (compare fig. 6 and 7).

Example 5

[0122] Screening of further epitope arrays led to the identification of constructs promoting the expression of the epitope SSX-2_{41-49} (SEQ ID NO. 13). In addition to some of the array elements defined in Example 3, the following additional elements were also used:

[0123] SSX-4_{57-65}:VMTKLGFKV (SEQ ID NO. 23) Array element F.

[0124] $PSMA_{730-739}$: RQIYVAAFTV (SEQ ID NO. 24) Array element G.

[0125] A construct, denoted CTLA02, encoding an initiator methionine and the array F-A-G-D-C-F-G-A, was found to successfully immunize HLA-A2 transgenic mice to generate a CTL response recognizing the peptide SSX-2_{41-49} (SEQ ID NO. 13).

[0126] As described above, it can be desirable to combine a sequence with substrate or liberation sequence function with one that can be processed into immune epitopes. Thus SSX-2_{15-183} (SEQ ID NO. 25) was combined with all or part of the array as follows:

[0127] CTLS1: F-A-G-D-C-F-G-A- SSX-2_{15-183} (SEQ ID NO. 26)

[0128] CTLS2: SSX-2_{15-183} - F-A-G-D-C-F-G-A (SEQ ID NO. 27)

[0129] CTLS3: F-A-G-D- SSX-2_{15-183} (SEQ ID NO. 28)

[0130] CTLS4: SSX-2_{15-183} -C-F-G-A (SEQ ID NO. 29).

[0131] All of the constructs except CTLS3 were able to induce CTL recognizing the peptide SSX-2_{41-49} (SEQ ID NO. 13). CTLS3 was the only one of these four constructs which did not include the second element A from CTLA02 suggesting that it was this second occurrence of the

element that provided substrate or liberation sequence function. In CTLS2 and CTLS4 the A element is at the C-terminal end of the array, as in CTLA02. In CTLS1 the A element is immediately followed by the SSX-2_{15-183} segment which begins with an alanine, a residue often found after proteasomal cleavage sites (Toes, R.E.M., et al., *J. Exp. Med.* 194:1-12, 2001). SEQ ID NO. 30 is the polynucleotide sequence encoding SEQ ID NO. 26 used in CTLS1, also called pCBP.

[0132] A portion of CTLS1 (SEQ ID NO. 26), encompassing array elements F-A-SSX-2_{15-23} with the sequence RQIYVAAFTV-*KASEKIFYV*-AQIPEKIQK (SEQ ID NO. 31), was made as a synthetic peptide and subjected to *in vitro* proteasomal digestion analysis with human immunoproteasome, utilizing both mass spectrometry and N-terminal pool sequencing. The observation that the C-terminus of the SSX-2_{41-49} epitope (SEQ ID NO. 13) was generated (see Figure 8) provided further evidence in support of substrate or liberation sequence function. The data in Figure 9 showed the differential processing of the SSX-2_{41-49} epitope, *KASEKIFYV* (SEQ ID NO. 13), in its native context, where the cleavage following the V was the predominant cleavage produced by housekeeping proteasome, while the immunoproteasome had several major cleavage sites elsewhere in the sequence. By moving this epitope into the context provided by SEQ ID NO. 31 the desired cleavage became a major one and its relative frequency compared to other immunoproteasome cleavages was increased (compare figs. 8 and 9). The data in figure 8B also showed the similarity in specificity of mouse and human immunoproteasome lending support to the usefulness of the transgenic mouse model to predict human antigen processing.

Example 6

[0133] Screening also revealed substrate or liberation sequence function for a tyrosinase epitope, $Tyr_{207-215}$ (SEQ ID NO. 32), as part of an array consisting of the sequence $[Tyr_{1-17}$- $Tyr_{207-215}]_4$, $[$MLLAVLYCLLWSFQTSA-FLPWHRLFL$]_4$, (SEQ ID NO. 33). The same vector backbone described above was used to express this array. This array differs from those of the other examples in that the Tyr_{1-17} segment, which was included as a source of immune epitopes, is used as a repeated element of the array. This is in contrast with the pattern shown in the other examples where sequence included as a source of immune epitopes and/or length occurred a single time at the beginning or end of the array, the remainder of which was made up of individual epitopes or shorter sequences.

Plasmid construction

[0134] The polynucleotide encoding SEQ ID NO. 33 was generated by assembly of annealed synthetic oligonucleotides. Four pairs of complementary oligonucleotides were synthesized which span the entire coding sequence with cohesive ends of the restriction sites of Afl II and EcoR I at either terminus. Each complementary pair of oligonucleotides were first annealed, the resultant DNA fragments were ligated stepwise, and the assembled DNA fragment was inserted into the same vector backbone described above pre-digested with Afl II/EcoR I. The construct was called CTLT2/pMEL and SEQ ID NO. 34 is the polynucleotide sequence used to encode SEQ ID NO. 33.

Example 7

Administration of a DNA plasmid formulation of a immunotherapeutic for melanoma to humans.

[0135] An MA2M melanoma vaccine with a sequence as described in Example 1 above, was formulated in 1% Benzyl alcohol, 1% ethyl alcohol, 0.5mM EDTA, citrate-phosphate, pH 7.6. Aliquots of 200, 400, and 600 μg DNA/ml were prepared for loading into MINIMED 407C infusion pumps. The catheter of a SILHOUETTE infusion set was placed into an inguinal lymph node visualized by ultrasound imaging. The pump and infusion set assembly was originally designed for the delivery of insulin to diabetics. The usual 17mm catheter was substituted with a 31mm catheter for this application. The infusion set was kept patent for 4 days (approximately 96 hours) with an infusion rate of about 25 μl/hour resulting in a total infused volume of approximately 2.4 ml. Thus the total administered dose per infusion was approximately 500, and 1000 μg; and can be 1500 μg, respectively, for the three concentrations described above. Following an infusion, subjects were given a 10 day rest period before starting a subsequent infusion. Given the continued residency of plasmid DNA in the lymph node after administration and the usual kinetics of CTL response following disappearance of antigen, this schedule will be sufficient to maintain the immunologic CTL response.

Example 8

[0136] SEQ ID NO. 22 is made as a synthetic peptide and packaged with a cationic lipid protein transfer reagent. The composition is infused directly into the inguinal lymph node (see example 7) at a rate of 200 to 600 μg of peptide per day for seven days, followed by seven days rest. An initial treatment of 3-8 cycles are conducted.

Example 9

[0137] A fusion protein is made by adding SEQ ID NO. 34 to the 3' end of a nucleotide sequence encoding herpes simplex virus 1 VP22 (SEQ ID NO. 42) in an appropriate mammalian expression vector; the vector used above is suitable. The vector is used to transform HEK 293 cells and 48 to 72 hours later the cells are pelleted, lysed and a soluble extract prepared. The fusion protein is purified by affinity chromatagraphy using an anti-VP22 monoclonal antibody. The purified fusion protein is administered intranodally at a rate of 10 to 100 μg per day for seven days, followed by seven days rest. An initial treatment of 3-8 cycles are conducted.

[0138] Further, the present invention can utilize various aspects of the following: U.S. Patent Application Nos. 09/380,534, filed on September 1, 1999, entitled A METHOD OF INDUCING A CTL RESPONSE; 09/776,232, filed on February 2, 2001, entitled METHOD OF INDUCING A CTL RESPONSE; 09/715,835, filed on November 16, 2000, entitled AVOIDANCE OF UNDESIRABLE REPLICATION INTERMEDIATES IN PLASMID PROPOGATION; 09/999,186, filed on November 7, 2001, entitled METHODS OF COMMERCIALIZING AN ANTIGEN; and Provisional U.S. Patent Application No 60/274,063, filed on March 7, 2001, entitled ANTI-NEOVASCULAR VACCINES FOR CANCER.

WHAT IS CLAIMED IS:

1. A method of identifying a polypeptide suitable for epitope liberation, the method comprising the steps of:

identifying an epitope of interest;

providing a substrate polypeptide sequence comprising the epitope, wherein the substrate polypeptide permits processing by a proteasome;

contacting the substrate polypeptide with a composition comprising the proteasome, under conditions that support processing of the substrate polypeptide by the proteasome; and

assaying for liberation of the epitope.

2. The method of claim 1, wherein the epitope is embedded in the substrate polypeptide.

3. The method of claim 1, wherein the epitope is a housekeeping epitope.

4. The method of claim 1, wherein the substrate polypeptide is a synthetic peptide.

5. The method of claim 1, wherein the substrate polypeptide is a fusion protein.

6. The method of claim 1, wherein the contacting step comprises immunization with the substrate polypeptide.

7. The method of claim 1, wherein the substrate polypeptide is encoded by a polynucleotide.

8. The method of claim 7, wherein the contacting step comprises immunization with a vector comprising the polynucleotide.

9. The method of claim 7, wherein the contacting step comprises transforming a cell with a vector comprising the polynucleotide.

10. The method of claim 1, wherein the proteasome processing takes place *in vitro*.

11. The method of claim 1, wherein the assaying step consists of a technique selected from the group consisting of mass spectrometry, N-terminal pool sequencing, and HPLC.

12. The method of claim 1, wherein the assaying step comprises a T cell target recognition assay.

13. The method of claim 1, wherein the substrate polypeptide further comprises an array of additional epitopes.

14. The method of claim 13, wherein the array comprises a housekeeping and an immune epitope.

15. The method of claim 1, wherein the substrate polypeptide further comprises an array of epitopes and epitope clusters.

16. The method of Claim 1, wherein the proteasome is an immune proteasome.

17. A vector comprising a housekeeping epitope expression cassette, wherein the housekeeping epitope is derived from a target-associated antigen, and wherein the housekeeping epitope is liberatable from a translation product of the cassette by immunoproteasome processing.

18. The vector of claim 17, wherein the expression cassette encodes an array of two or more epitopes or at least one epitope and at least one epitope cluster.

19. The vector of claim 17, wherein the target-associated antigen is an antigen derived from or associated with a tumor or an intracellular parasite.

20. A method of activating a T cell comprising contacting the vector of claim 17 with an APC and contacting said APC with a T cell.

21. A substrate polypeptide comprising a housekeeping epitope wherein the housekeeping epitope can be liberated by immunoproteasome processing in a pAPC.

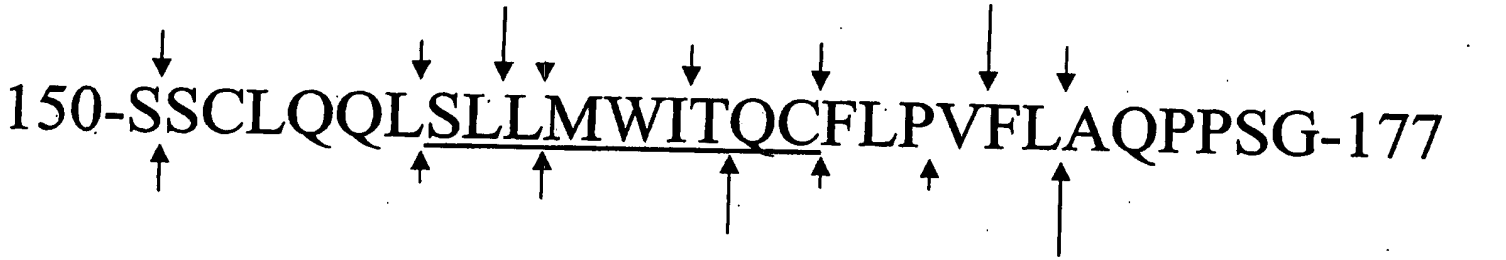
Figure 6

NY-ESO-1 150-177



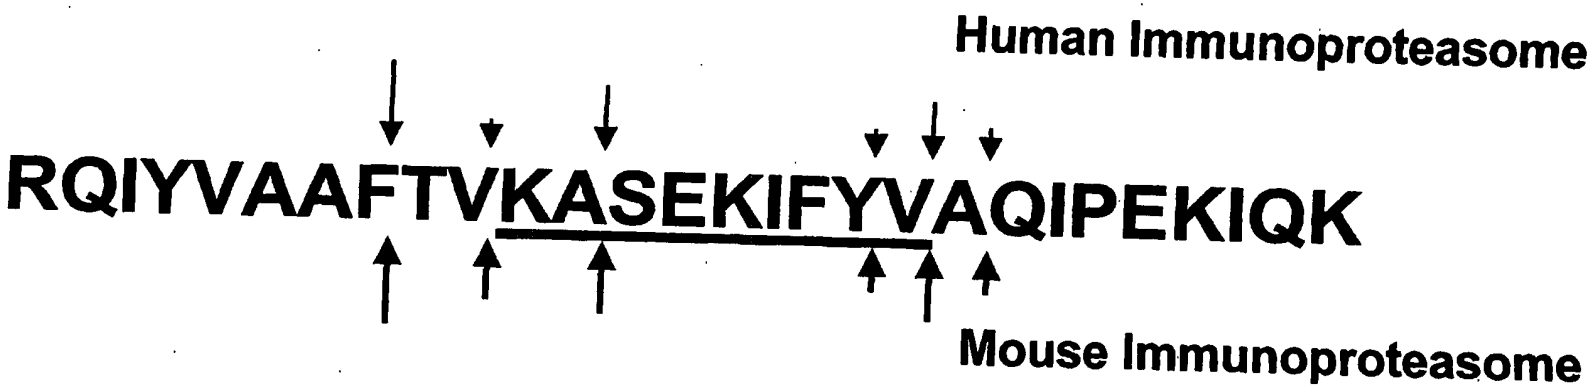
Cleavage sites in the NY-ESO-1 150-177 substrate upon digestion with 20S housekeeping proteasome (upper arrows) and immunoproteasome (lower arrows). The size of each arrow indicates the efficiency of cleavage as determined by pool sequencing analysis. The epitope NY-ESO-1 157-165 (SEQ ID NO. 12) is underlined.

Figure 7

Human Immunoproteasome Digest of SEQ ID NO. 31

Cleavage sites in the CTLS1-2 substrate upon digestion with immunoproteasome (isolated from γ-IFN treated HeLa cells).. The sequence of epitope SSX2 41-49 (SEQ ID NO. 13) is underlined.

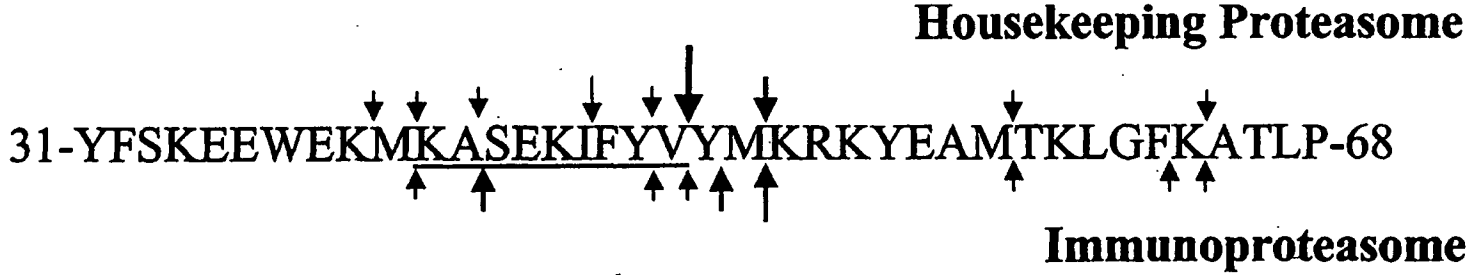
Figure 8A



Comparisons of CTLS1-2 substrate (SEQ ID NO. 31) digested by 20S human immunoproteasome versus mouse immunoproteasome. The size of each arrow indicates the efficiency of cleavage as determined by N-terminal pool sequencing analysis. The sequence of epitope SSX2 41-49 (SEQ ID NO. 13) is underlined.

Figure 8B

SSX2 31-68



Cleavage sites in the SSX2 31-68 substrate upon digestion with 20S housekeeping proteasome (isolated from erythrocytes) (upper arrows) and immunoproteasome (isolated from γ-IFN treated Hela cells) (lower arrows). The size of each arrow indicates the efficiency of cleavage as determined by N-terminal pool sequencing analysis. The epitope SSX2 41-49 (SEQ ID NO. 13) is underlined.
